The valence state of  $\text{UTe}_2$  was studied by core-level photoelectron spectroscopy. The main peak position of the U 4f core-level spectrum of  $\text{UTe}_2$  coincides with that of  $\text{UB}_2$ , which is an itinerant compound with a nearly  $5f^3$  configuration. However, the main peak of  $\text{UTe}_2$  is broader than that of  $\text{UB}_2$ , and satellite structures are observed in the higher binding energy side of the main peak, which are characteristics of mixed-valence uranium compounds. These results suggest that the U 5f state in  $\text{UTe}_2$  is in a mixed valence state with a dominant contribution from the itinerant  $5f^3$  configuration.

The unconventional superconductivity in  $\text{UTe}_2$  has attracted much attention in recent years.<sup>1,2)</sup> Its electronic structure is essential to understand the origin of its superconductivity, and angle resolved photoelectron spectroscopy (ARPES) has been applied using soft X-ray (SX,  $h\nu = 565 - 800$  eV)<sup>3)</sup> and vacuum ultraviolet (VUV,  $h\nu = 30 - 150$  eV)<sup>4)</sup> synchrotron radiation. However, these two ARPES studies presented contradicting views of the electronic structure of  $\text{UTe}_2$ : The SX ARPES study concluded that the band-structure calculation treating U 5f states as valence electrons can explain the overall electronic structure of  $\text{UTe}_2$ <sup>3)</sup> while the VUV ARPES study argued that the near- $E_F$  electronic structure is very similar to that of the band-structure calculation of  $\text{ThTe}_2$  although there exist heavy bands around the Z point.<sup>4)</sup> In addition, the partial U 5f density of states (DOS) obtained by resonant photoelectron spectroscopy (RPES) at the  $4d - 5f$  absorption edge ( $h\nu = 736$  eV) has a dominant sharp peak at the Fermi energy,<sup>3)</sup> while the on-resonant RPES spectrum measured at the  $5d - 5f$  absorption edge ( $h\nu = 98$  eV) has a dominant peak at a higher binding energy of  $E_B \sim 0.7$  eV.<sup>4)</sup> To solve this discrepancy, additional electronic structure studies on  $\text{UTe}_2$  are required. Recently, Thomas *et al.* reported X-ray absorption spectrum (XAS) of  $\text{UTe}_2$  under ambient and high pressures.<sup>5)</sup> They argued that  $\text{UTe}_2$  exhibits intermediate valence at ambient pressure, suggesting that the U 5f state in  $\text{UTe}_2$  is hybridized with the ligand states. In the present study, we further studied the U 5f valence state of  $\text{UTe}_2$  using core-level spectroscopy, which has the ability to probe the valence state of the local uranium site.<sup>6,7)</sup> The U 4f spectrum of  $\text{UTe}_2$  was compared with that of a typical itinerant compound,  $\text{UB}_2$ , and localized compound,  $\text{UPd}_3$ , as well as ferromagnetic superconductors  $\text{UGe}_2$ ,  $\text{UCoGe}$ ,  $\text{URhGe}$ , and  $\text{UPt}_3$ .

Photoemission experiments were conducted on the SX beamline BL23SU at SPring-8.<sup>8)</sup> The overall energy resolution in the angle-integrated photoelectron spectroscopy exper-

Data of  $\text{UB}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ ,  $\text{URhGe}$ ,  $\text{UPt}_3$ , and  $\text{UPd}_3$  are depicted from Refs 6 and 7. (a) U 4f core-level spectra of  $\text{UB}_2$ ,  $\text{UTe}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ ,  $\text{URhGe}$ ,  $\text{UPt}_3$ , and  $\text{UPd}_3$ . (b) Blow up of the main peaks of U  $4f_{7/2}$  spectra and their negative second derivatives

iments at  $h\nu = 800$  eV was approximately 140 meV. The kinetic energy of photoelectrons is about 400 eV, which is considered to have enough bulk sensitivity since the U 4f spectra of  $\text{URu}_2\text{Si}_2$  measured at  $h\nu = 800$  eV<sup>6,7)</sup> and  $h\nu = 5945$  eV<sup>9)</sup> are essentially identical. The sample temperature was kept at 20 K for all measurements. Other experimental conditions are described in Ref. 3.

Figure 1 (a) presents a comparison of the U 4f core-level spectra of  $\text{UB}_2$ ,  $\text{UTe}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ ,  $\text{URhGe}$ ,  $\text{UPt}_3$ , and  $\text{UPd}_3$ . Their negative second derivatives of U  $4f_{7/2}$  spectra are also provided in Fig. 1 (b) to indicate the locations of peaks in the spectra. Data of  $\text{UB}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ ,  $\text{URhGe}$ ,  $\text{UPt}_3$ , and  $\text{UPd}_3$  are depicted from Refs 6 and 7.  $\text{UB}_2$  and  $\text{UPd}_3$  are typical itinerant and localized compounds, respectively. The band structure and Fermi surface of  $\text{UB}_2$  are well explained by the band-structure calculation treating all U 5f electrons as itinerant.<sup>10)</sup> The occupation number of the U 5f state within the Muffin-Tin sphere is 2.82 in the calculation; thus, the local U 5f electronic configuration of  $\text{UB}_2$  can be considered the dominant  $5f^3$  configuration. In contrast,  $\text{UPd}_3$  is a uranium compound with a localized  $5f^2$  configuration.

These spectra all generally consist of a dominant main peak located at  $E_B = 377 - 379$  eV and a broad satellite structure distributed at  $E_B = 381 - 387$  eV. These complex spectral shape originate from the transition from the ground state to multiple final states with different local U 5f electronic configurations.<sup>11)</sup> There are several theoretical models of the origin of the U 4f spectral profiles;<sup>12,13)</sup> however, the quantitative analysis has not yet been established. Nevertheless, dif-

\*fujimori@spring8.or.jp

ferent final states have different binding energies, which can be used to identify the local electronic configuration in the ground state. Here, we discuss the electronic structure of  $\text{UTe}_2$  based on a comparison with typical uranium compounds.

The main peak positions of  $\text{UTe}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$  are almost identical ( $E_B = 377 - 377.3$  eV), and have a similar asymmetric peak structure with a long tail toward higher binding energies. Their main peak positions are very similar to that of the itinerant U  $5f$  compound  $\text{UB}_2$  (designated as A in Fig. 1 (b)), and are very different from the spectrum of  $\text{UPd}_3$  (designated as B in Fig. 1 (b)). This indicates that the dominant final state configurations in  $\text{UTe}_2$  as well as  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$  are identical to that of  $\text{UB}_2$ , and the dominant U  $5f$  configurations in the ground states of  $\text{UTe}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$  are also similar to that of  $\text{UB}_2$ . In contrast, the main peaks of  $\text{UTe}_2$  as well as ferromagnetic superconductors are broader than that of  $\text{UB}_2$ . As seen in the spectrum of  $\text{UPd}_3$ , the main peak consists of two peaks ( $E_B = 378.9$  and  $377.2$  eV), and the broadening in the main peaks of  $\text{UTe}_2$ ,  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$  may originate from a small contribution from the  $\text{UPd}_3$ -type peak on the higher binding energy side of the main peaks, although this has not been resolved experimentally. Moreover, the core-level spectrum of  $\text{UTe}_2$  is accompanied by a satellite, which has been observed in the U  $4f$  core-level spectra of strongly-correlated or localized  $5f^2$  uranium compounds. Thus, these results indicate that the ground state of  $\text{UTe}_2$  is a mixed valence state with a dominant contribution from the  $5f^3$  configuration and some contribution from the  $5f^2$  configuration. These results are consistent with the result of SX-ARPES study<sup>3)</sup> and the XAS study.<sup>5)</sup> In addition, the core-level spectral shape of  $\text{UTe}_2$  is similar to that of  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$ , which have essentially itinerant but correlated U  $5f$  states,<sup>7, 14, 15)</sup> suggesting that  $\text{UTe}_2$  should be similar to them.

Here, we consider the relationship between the present result and the results of other studies on the electronic structure of  $\text{UTe}_2$ . In density functional theory (DFT) plus Hubbard  $U$  (DFT+ $U$ ) and generalized gradient approximation plus  $U$  (GGA+ $U$ ) with  $U \geq 2$  eV, quasi-two-dimensional Fermi surfaces have been predicted.<sup>16, 17)</sup> In these calculations, most of the U  $5f$  weight was away from the Fermi level by the introduction of the  $U$ , and the topology of the Fermi surface becomes almost identical to that of the DFT calculation for  $\text{ThTe}_2$ . Experimentally, the VUV ARPES study reported very similar near- $E_F$  electronic structure, although the existence of a heavy band around the Z point was claimed.<sup>4)</sup> Furthermore, the VUV-RPES spectrum was interpreted based on the ground state with the dominant  $5f^2$  Hund's rule ground state, which is based on the slightly mixed valent but essentially localized  $5f^2$  state.<sup>4)</sup> In such situation, its core-level spectrum should be similar to those of the localized compound  $\text{UPd}_3$  or weakly hybridized compound  $\text{UPt}_3$ . However, the present result indicates that the hybridized (itinerant)  $5f^3$  configuration is dominant in the ground state of  $\text{UTe}_2$ , and the U  $5f$  states should thus make dominant contributions to the state at the Fermi level. The very different nature of U  $5f$  states observed in the VUV ARPES study may originate from the enhanced surface sensitivity of VUV PES ( $\lesssim 5$  Å) compared with SX-PES ( $\gtrsim 15$  Å), as similar discrepancies have been observed in strongly correlated  $f$ -electron materials.<sup>7, 18, 19)</sup>

In summary, we applied core-level spectroscopy to  $\text{UTe}_2$ . A

comparison between the core-level spectral shape of  $\text{UTe}_2$  and that of typical compounds demonstrated that the local electronic configuration of the U  $5f$  state in  $\text{UTe}_2$  is in the mixed valence state with a dominant contribution from the  $5f^3$  configuration. Furthermore, the spectrum of  $\text{UTe}_2$  is very similar to that of  $\text{UGe}_2$ ,  $\text{UCoGe}$ , and  $\text{URhGe}$ , suggesting that U  $5f$  should essentially have itinerant character, although there exist electron correlation effects. The result indicates that the topology of the Fermi surface of  $\text{UTe}_2$  should be considerably different from the localized model, such as the DFT calculation for  $\text{ThTe}_2$ .
