Abstract

We show some examples of calculations of massless and massive Feynman integrals.

1 Introduction

At present, the calculation of the Feynman integrals (FIs) provides basic information both on the properties of the experimentally investigated processes and on the characteristics of the physical models under study. Calculations of the matrix elements of the cross sections of the processes under study depend on the internal properties of particles participating in the interactions, such as masses, spins, etc. and, strictly speaking, require the calculation of Feynman integrals, including those with massive propagators. Depending on the kinematics of the processes under study, the values of some masses can be neglected. Studying the characteristics of physical models (for example, critical parameters, anomalous particle sizes and operators) usually requires the calculation of massless Feynman integrals, which have a much simpler structure. This allows obtaining results for these characteristics in high orders of the perturbation theory.

I would like to draw your attention to the fact that when calculating FIs, it is recommended to use analytical methods whenever possible. The point is that the numerical calculation of FIs is severely limited due to the singularities arising in them, and also (especially for gauge theories) due to strong mutual cancellations between contributions from different diagrams or even between parts of the same diagram.

Note that when using the dimensional regularization [1], i.e. when calculating the FIs for an arbitrary dimension of space, once found diagrams for some model of a field theory (or process) can be applied to other models (or processes), since the main object of study is the so-called scalar master integrals. Consequently, the complexity of analytical calculations of FI is compensated by their versatility as applied to various quantum field models.

Note also the fact that the calculation of complicated diagrams may be of some independent interest. For example, the use of non-trivial identities, such as the "uniqueness" relation [2, 3], can provide information (see [4, 5]) about the properties of some integrals and series which are not yet in the reference literature. For example, the calculations of the same Feynman integral carried out in [5] and [6], using various methods, have made it possible to find a previously unknown relationship between hypergeometric functions with arguments 1 and -1 . This relation has been neatly proven quite recently [7].

Recently, many powerful original methods for calculating Feynman integrals have appeared (see, for example, a recent reviews in Refs. [8, 9]), which are often inferior in breadth of application to standard methods such as the α -representation and the Feynman parameter

technique (see, for example, [10, 11]), however, can significantly increase the computation accuracy for a limited set of quantities (or processes).

This short article is devoted to the consideration of two FIs, one with massless propagators, and the other with massive propagators, the calculations of which just demonstrate the effectiveness of modern methods for calculating Feynman diagrams.

In the massless case, we will consider a single 5-loop master diagram that contributes to the β -function of the φ^4 -model. In the initial calculations [12] of the 5-loop correction to the β -function of the φ^4 -model, the results of four FIs were found only numerically. Their analytical results were obtained by Kazakov (see [4, 5]), but they have been published without any intermediate results. Moreover, all calculations were performed in x -space, which can make them difficult to understand. Recently, two of the four diagrams have been exactly recalculated in [8] in p -space and are presented with intermediate calculations. In Section 3, we provide a neat calculation for the third diagram.

In the massive case, in Section 5, we consider the computation of one of master-integrals [13] contributing to the relationship between the \overline{MS} -mass and the pole-mass of the Higgs boson in the Standard Model in the limit of heavy Higgs. Results for the master-integral, along with the results for other master-integrals were calculated [14] early 2000s, but unfortunately they have not been published. Some sets of variables for integration are presented in Appendix A.

2 Basic formulas for massless diagrams

Let us briefly consider the rules for calculation of massless diagrams. All calculations are carried out in momentum space with $d = 4 - 2\varepsilon$.

Propagator is represented as

$$\frac{1}{(q^2)^\alpha} \equiv \frac{1}{q^{2\alpha}} = \overrightarrow{q} \text{---} \overset{\bullet}{\text{---}} \underset{\alpha}{\text{---}} \overset{\bullet}{\text{---}} . \quad (1)$$

where α is called the line index.

The following formulas hold.

A. For simple chain:

$$\frac{1}{q^{2\alpha_1}} \frac{1}{q^{2\alpha_2}} = \frac{1}{q^{2(\alpha_1+\alpha_2)}} ,$$

or graphically

$$\overrightarrow{q} \text{---} \overset{\bullet}{\text{---}} \underset{\alpha_1}{\text{---}} \overset{\bullet}{\text{---}} \underset{\alpha_2}{\text{---}} \overset{\bullet}{\text{---}} = \overrightarrow{q} \text{---} \overset{\bullet}{\text{---}} \underset{\alpha_1 + \alpha_2}{\text{---}} \overset{\bullet}{\text{---}} , \quad (2)$$

i.e. the product of propagators is equivalent to a new propagator with an index equal to the sum of the indices of the original propagators.

B. A simple loop can be integrated as

$$\int \frac{Dk \mu^{2\varepsilon}}{(q-k)^{2\alpha_1} k^{2\alpha_2}} = N_d \frac{\mu^{2\varepsilon}}{q^{2(\alpha_1+\alpha_2-d/2)}} A(\alpha_1, \alpha_2),$$

where

$$Dk = \frac{d^d k}{(2\pi)^d} \quad (3)$$

is usual integration in Euclidean measure and

$$N_d = \frac{1}{(4\pi)^{d/2}}, \quad A(\alpha, \beta) = \frac{a(\alpha)a(\beta)}{a(\alpha+\beta-d/2)}, \quad a(\alpha) = \frac{\Gamma(\tilde{\alpha})}{\Gamma(\alpha)}, \quad \tilde{\alpha} = \frac{d}{2} - \alpha. \quad (4)$$

It is convenient to rewrite the equation graphically as

$$\text{Loop diagram} = N_d \mu^{2\varepsilon} A(\alpha_1, \alpha_2) \text{Chain diagram} \quad (5)$$

So, all massless diagrams, which can be expressed as combinations of loops and chains can be evaluated immediately, even when some indices have arbitrary values (see Refs. [15, 16, 17]). However, starting already with the two-loop level, there are diagrams, which cannot be expressed as combinations of loops and chains (see, for example, Fig.1 in Ref. [9]). For these cases there are additional rules.

C. When $\sum \alpha_i = d$, there is so-called uniqueness ratio [2, 3, 4] for the triangle with indices α_i ($i = 1, 2, 3$)

$$\text{Triangle diagram} \stackrel{\sum \alpha_i = d}{=} N_d \mu^{2\varepsilon} A(\alpha_2, \alpha_3) \text{Chain diagram} \quad (6)$$

The results (6) can be exactly obtained in the following way: perform an inversion $q_i \rightarrow 1/q_i$ ($i = 1, 2, 3$), $k \rightarrow 1/k$ in the subintegral expression and in the integral measure. The inversion keeps angles between momenta. After the inversion, one propagator is cancelled because $\sum \alpha_i = d$ and the l.h.s. becomes to be equal to a loop. Evaluating it using the rule (5) and returning after it to the initial momenta, we recover the rule (6).

D. For any triangle with indices α_i ($i = 1, 2, 3$) there is the following relation, which is based on integration by parts (IBP) procedure [3, 18]. This paper does not use the IBP procedure for massless charts and therefore is not provided here. However, it can be obtained directly from the IBP in the massive case (see (48) below) by setting all masses to zero.

E. Using equation (48) with zero masses allows you to change the indices of the line diagrams by an integer. One can also change line indices using the point group of transformations [3, 19]. The elements of the group are: a) the transition to momentum presentation, b) conformal inversion transformation $p \rightarrow p' = p/p^2$, c) a special series of transformations that makes it possible to make one of the vertices unique, and then apply relation (6) to it.

Note that the presence of momenta, and especially the product of momenta in the numerators of the propagators, significantly complicates the FI results and requires generalization of the rules for their calculation (see, for example, Refs [20, 21]. However, consideration of this case is beyond the scope of this work.

3 kR' -operation

Calculation of massless diagrams is most important for calculating critical exponents of models and theories, such as anomalous dimensions and β -functions. One of the most important recipes is the Bogolyubov-Parasyuk-Hepp-Zimmermann (BPHZ) R -operation [22], which extracts all singularities of any Feynman diagram. Formally, it has the form

$$R[FI] = FI - kR'[FI], \quad (7)$$

where the kR' -operation takes into account all the singularities of the subgraphs of the considered diagram, except for the singularities of the diagram itself. A very important property of the kR' -operations is the independence of the result of its application to any FI diagram (i.e. $kR'[FI]$) from the external momenta and masses of this FI diagram. This independence is the basis of the infra-red rearrangement approach [23] (see also Refs. [24] and [25]), which allows us to consider FI with the minimum possible set of masses and external momenta: neglecting masses and momenta should not lead to the appearance of infrared singularities. The ability to remove and change external momenta is widely used (see, for example, [26] and references and discussions therein). We show it in our example below, where we will consider in detail the computation of the singular structure of a 5-loop diagram that contributes to the β -function of the φ^4 -model.

To show the applicability of the kR' -operation, it is convenient to start with the one-loop and two-loop examples.

One loop. Putting $\alpha_1 = \alpha_2 = 1$ in Eq. (5), we have

$$= N_d A(1, 1) \frac{\mu^{2\varepsilon}}{q^{2\varepsilon}} = N_4 \frac{\Gamma^2(1 - \varepsilon)}{\varepsilon \Gamma(2 - 2\varepsilon)} \frac{\bar{\mu}^{2\varepsilon}}{q^{2\varepsilon}}, \quad (8)$$

where $\bar{\mu}$ is the scale in the \overline{MS} -scheme, defined as

$$\bar{\mu}^{2\varepsilon} = \mu^{2\varepsilon} (4\pi)^\varepsilon \Gamma(1 + \varepsilon). \quad (9)$$

Then kR' -operation, which in the one-loop case is equal to k -operation, because no subgraphs, where k -operation is an extraction of the singular part, is the one:

$$k \left[\text{diagram} \right] = N_4 \frac{1}{\varepsilon}, \quad (10)$$

which, of course, is q^2 -independent.

Two loops. Consider the diagram

$$\text{diagram} = N_d^2 A(1, 1) A(1, 1 + \varepsilon) \frac{\mu^{4\varepsilon}}{q^{4\varepsilon}} = \frac{N_4^2}{2\varepsilon^2(1 - 2\varepsilon)} \frac{\Gamma^3(1 - \varepsilon)\Gamma(1 + 2\varepsilon)}{\Gamma(2 - 3\varepsilon)\Gamma^2(1 + \varepsilon)} \frac{\bar{\mu}^{2\varepsilon}}{q^{2\varepsilon}}. \quad (11)$$

The R' -operation extract the singularities of subgraphs. In the considered case, we have the singular internal loop, which singularity is shown in Eq. (10). So, the R' -operation of the considered two-loop diagram has the following form

$$R' \left[\text{diagram} \right] = \text{diagram} - N_4 \frac{1}{\varepsilon} \text{diagram}. \quad (12)$$

Evaluating loops in the r.h.s. of (12) and taking its singular parts (by the k -operation), we have

$$\begin{aligned} kR' \left[\text{diagram} \right] &= k \left[\text{diagram} - N_4 \frac{1}{\varepsilon} \text{diagram} \right] \\ &= N_4^2 \left[\frac{1}{2\varepsilon^2} \left(1 + (5 + 2L)\varepsilon \right) - \frac{1}{\varepsilon^2} \left(1 + (2 + L)\varepsilon \right) \right] = N_4^2 \left[-\frac{1}{2\varepsilon^2} + \frac{1}{2\varepsilon} \right], \end{aligned} \quad (13)$$

where

$$L = \ln \left(\frac{\bar{\mu}^2}{q^2} \right). \quad (14)$$

As we can see the r.h.s. of (13) is q^2 -independent.

Fifth loops. Consider the fifth-loop diagram contributed to β -function of φ^4 -model. The kR' -operation of the diagram has the following form

$$kR' \left[\text{Diagram 1} \right] = k \left[\text{Diagram 2} - N_4 \frac{1}{\varepsilon} \text{Diagram 3} \right], \quad (15)$$

which contains the diagram itself and the counter-term, corresponding the singularity of the internal loop.

Since the r.h.s. is q^2 -independent, we can cancel the external momenta in the considered points and put it to the points A and B:

$$kR' \left[\text{Diagram 1} \right] = k \left[\text{Diagram 2} - N_4 \frac{1}{\varepsilon} \text{Diagram 3} \right]. \quad (16)$$

Taking the external momenta in the points A and B as it was done in the r.h.s, we have the following form for the considered diagrams

$$\frac{A}{\vec{q}} \text{Diagram 1} - \frac{N_4}{\varepsilon} \frac{A}{\vec{q}} \text{Diagram 2} = N_d C_4 A(1, 1+4\varepsilon) \left(\frac{\mu^2}{q^2} \right)^{5\varepsilon} - N_d N_4 \frac{C_3}{\varepsilon} A(1, 1+3\varepsilon) \left(\frac{\mu^2}{q^2} \right)^{4\varepsilon}, \quad (17)$$

where the integrals I_4 and I_3 are the internal blocks, which produce the diagrams in the r.h.s. of (16) after integration of the blocks with the propagator between A and B. From the dimensional property, the integrals I_4 and I_3 can be represented in the following form

$$\frac{A}{\vec{q}} \text{Diagram 1} = N_d^4 C_4 \frac{(\mu^2)^{4\varepsilon}}{(q^2)^{1+4\varepsilon}}, \quad \frac{A}{\vec{q}} \text{Diagram 2} = N_d^3 C_3 \frac{(\mu^2)^{3\varepsilon}}{(q^2)^{1+3\varepsilon}}, \quad (18)$$

where C_4 and C_3 are the coefficient functions of the integrals I_4 and I_3 .

So, we get that

$$kR' \left[\text{Diagram 1} \right] = N_4 \text{Sing} \left[C_4 A(1, 1+4\varepsilon) - \frac{C_3}{\varepsilon} A(1, 1+3\varepsilon) \right], \quad (19)$$

where all q^2 -dependence is cancelled in the r.h.s. singular terms.

For the similar diagram but with the index $1 - \varepsilon$ in the line between A and B, we have the following

$$kR' \left[\text{Diagram} \right] = N_4 \text{Sing} \left[C_4 A(1 - \varepsilon, 1 + 4\varepsilon) - \frac{C_3}{\varepsilon} A(1 - \varepsilon, 1 + 3\varepsilon) \right]. \quad (20)$$

We would like to note that in this diagram we can represent, as a outer line, the line between points A and C, that is, we get

$$kR' \left[\text{Diagram} \right] = k \left[\text{Diagram 1} - \frac{1}{\varepsilon} \frac{1}{q} \text{Diagram 2} \right] \quad (21)$$

and, thus,

$$kR' \left[\text{Diagram} \right] = N_4 \text{Sing} \left[C_{4,1} A(1, 1 + 3\varepsilon) - \frac{C_{3,1}}{\varepsilon} A(1, 1 + 2\varepsilon) \right], \quad (22)$$

where $C_{4,1}$ and $C_{3,1}$ are the coefficient functions of the integrals $I_{4,1}$ and $I_{3,1}$, which are the internal blocks, which produce the diagrams in the r.h.s. of (21) after integration of the blocks with the propagator between A and C. From the dimensional property, the integrals $I_{4,1}$ and $I_{3,1}$ can be represented in the following form

$$\frac{A}{\vec{q}} \text{---} I_{4,1} \text{---} C = N_d^4 C_{4,1} \frac{(\mu^2)^{4\varepsilon}}{(q^2)^{1+3\varepsilon}}, \quad \frac{A}{\vec{q}} \text{---} I_{3,1} \text{---} C = N_d^3 C_{3,1} \frac{(\mu^2)^{3\varepsilon}}{(q^2)^{1+2\varepsilon}}, \quad (23)$$

because they contain one line with the index $1 - \varepsilon$.

Now we consider the diagram, similar to the initial one, but with lines between A and B and A and C, having the indices $1 - \varepsilon$. Taking as above, the line between A and C as an external one, we have the following results

$$kR' \left[\frac{D}{\vec{q}} \right] = N_4 \text{Sing} \left[C_{4,1} A(1-\varepsilon, 1+3\varepsilon) - \frac{C_{3,1}}{\varepsilon} A(1-\varepsilon, 1+2\varepsilon) \right]. \quad (24)$$

The l.h.s. diagram, which contains two lines with the index $1-\varepsilon$, can be evaluated exactly. Indeed, we can represent the r.h.s. diagrams as combinations blocks, containing two lines with the index $1-\varepsilon$, and some additional line between D and E:

$$kR' \left[\frac{D}{\vec{q}} \right] = k \left[\frac{D}{\vec{q}} \right] - \frac{1}{\varepsilon} \frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] = N_d \text{Sing} \left[C_{4,2} A(1, 1+2\varepsilon) - \frac{C_{3,2}}{\varepsilon} A(1, 1+\varepsilon) \right], \quad (25)$$

where $C_{4,2}$ and $C_{3,2}$ are the coefficient functions of the integrals $I_{4,2}$ and $I_{3,2}$, which can be obtained from the diagrams in the r.h.s. taking out the line between D and E. Since they have two lines with the index $1-\varepsilon$, from dimensional properties the integrals $I_{4,2}$ and $I_{3,2}$ can be imagined as

$$\frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] = N_d^4 C_{4,2} \frac{(\mu^2)^{4\varepsilon}}{(q^2)^{1+2\varepsilon}}, \quad \frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] = N_d^3 C_{3,2} \frac{(\mu^2)^{3\varepsilon}}{(q^2)^{1+\varepsilon}}, \quad (26)$$

Now we consider the integral $I_{4,2}$. After integrating of the internal loop, we have

$$\frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] = N_d A(1, 1) \frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right]. \quad (27)$$

The vertex DAC in the r.h.s. diagram is unical and, thus, it can be replaced by triangle as it was shown in eq. (6). So, we have

$$N_d A(1, 1) \frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] = \frac{D}{\vec{q}} \left[\frac{E}{\vec{q}} \right] \quad (28)$$

Now the triangle CBE in the r.h.s. diagram is unical and, thus, it can be replaced by vertex in an agreement with (6):

$$\text{Diagram (left)} = N_d A(1, 1) \text{Diagram (right)} \quad (29)$$

So, finally we have

$$\text{Diagram (left)} = N_d A(1, 1) J_1^{(1)} \frac{1}{q^{2ε}}, \quad (30)$$

where the integral $J_1^{(1)}$ is the table one (see Ref. [8])¹: $J_1^{(1)} = J_1(1, 1, 1, 1, 1, 1 - \varepsilon, 1 - \varepsilon)$. Here

$$J_1(a_1, a_2, a_3, a_4, a_5, a_6, a_7)(q^2) = \text{Diagram} = N_4^3 C_1(a_1, a_2, a_3, a_4, a_5, a_6, a_7) \frac{(\bar{\mu}^2)^{3\varepsilon}}{(q^2)^{a-3d/2}}, \quad (31)$$

where $a = \sum_{k=1}^7 a_k$, and

$$C_1(a_1, a_2, a_3, a_4, a_5, a_6, a_7) = \frac{1}{1 - 2\varepsilon} [B_0 \zeta_5 + (B_1 \zeta_6 + B_2 \zeta_3^3) \varepsilon + O(\varepsilon^2)] \quad (32)$$

with

$$a_i = 1 + \bar{a}_i \varepsilon, \quad B_0 = 20, \quad B_1 = 50, \quad B_2 = 20 + 6 \sum_{k=4}^7 \bar{a}_k. \quad (33)$$

It is convenient to write $C_1^{(1)} = C_1(1, 1, 1, 1, 1, 1 - \varepsilon, 1 - \varepsilon)$ as

$$C_1^{(1)} = C_1^{(0)} \left(1 - \frac{3\zeta_3^2}{5\zeta_5} \varepsilon \right), \quad (34)$$

¹Note that the results obtained in Ref. [8] are a simple recalculation of the corresponding results [4, 5] found in the x -space. For recalculation, it is convenient to use the concept of the so-called dual diagrams (see, for example, Refs. [20, 21]), which are obtained from the original ones by replacing all momenta with coordinates. With this replacement, the results of the FIs themselves remain unchanged, and only their graphical representation changes. In general, dual diagrams are used [20, 21] in the massless case, but they can also be used [27, 28] for propagators with masses.

where

$$C_1^{(0)} = C_1(1, 1, 1, 1, 1, 1, 1) = \frac{10}{1 - 2\varepsilon} [2\zeta_5 + (5\zeta_6 + 2\zeta_3^3)\varepsilon + O(\varepsilon^2)] \quad (35)$$

The counter-terms $I_3(q^2)$, $I_{3,1}(q^2)$ and $I_{3,2}(q^2)$ can be expressed also through $J_1(a_1, a_2, a_3, a_4, a_5, a_6, a_7)$ in the following from:

$$I_{3,2}(q^2) = J_1(1, 1 - \varepsilon, 1 - \varepsilon, 1, 1, 1, 1), I_{3,1}(q^2) = J_1(1 - \varepsilon, 1, 1, 1, 1, 1, 1), I_3(q^2) = J_1(1, 1, 1, 1, 1, 1, 1). \quad (36)$$

So, within the accuracy $O(\varepsilon^2)$ their coefficient functions are coincide:

$$C_3 = C_{3,1} + O(\varepsilon^2) = C_{3,2} + O(\varepsilon^2) = C_1^{(0)} + O(\varepsilon^2). \quad (37)$$

Taking into account above relations and the results for the one-loop results $A(\alpha, \beta)$, it is possible to show that within the accuracy $O(\varepsilon^2)$ the results for four-loop coefficient functions are also coincide. Indeed,

$$C_{4,1} = C_{4,2} \frac{A(1, 1 + 2\varepsilon)}{A(1 - \varepsilon, 1 + 3\varepsilon)} - \frac{C_{3,1}}{\varepsilon} \frac{e^{(-L\varepsilon)}}{A(1 - \varepsilon, 1 + 3\varepsilon)} [A(1, 1 + \varepsilon) - A(1 - \varepsilon, 1 + 2\varepsilon)] + O(\varepsilon^2),$$

$$C_4 = C_{4,1} \frac{A(1, 1 + 3\varepsilon)}{A(1 - \varepsilon, 1 + 4\varepsilon)} - \frac{C_3}{\varepsilon} \frac{e^{(-L\varepsilon)}}{A(1 - \varepsilon, 1 + 4\varepsilon)} [A(1, 1 + 2\varepsilon) - A(1 - \varepsilon, 1 + 3\varepsilon)] + O(\varepsilon^2)$$

and the terms $\sim C_{3,1}$ and $\sim C_3$ are suppressed and we have

$$C_4 = C_{4,1} + O(\varepsilon^2) = C_{4,2} + O(\varepsilon^2) \quad (38)$$

and, thus,

$$C_4 = C_1^{(1)} + O(\varepsilon^2) = C_1^{(0)} \left(1 + \frac{3\zeta_3^2}{10\zeta_5} \varepsilon \right) + O(\varepsilon^2) \quad (39)$$

So, for the initial diagrams, shown in the r.h.s of eq. (15), using the r.h.s of (19), we have

$$= N_4^5 \frac{C_1^{(1)}}{5\varepsilon^2(1 - 2\varepsilon)(1 - 6\varepsilon)} \left(\frac{\bar{\mu}^2}{q^2} \right)^{5\varepsilon} \quad (40)$$

and

$$= N_4^4 \frac{C_1^{(0)}}{4\varepsilon^2(1 - 5\varepsilon)} \left(\frac{\bar{\mu}^2}{q^2} \right)^{4\varepsilon}. \quad (41)$$

Thus, for the initial combination shown in (15), we have

$$(4\pi)^{10} kR' \left[\text{Diagram} \right] = \text{Sing} \left[\frac{C_1^{(1)} e^{5L\varepsilon}}{5\varepsilon^2(1-2\varepsilon)(1-6\varepsilon)} - \frac{C_1^{(0)} e^{4L\varepsilon}}{4\varepsilon^2(1-5\varepsilon)} \right], \quad (42)$$

where L is give in eq. (14). Taking the results for $C_1^{(1)}$ and $C_1^{(0)}$, given in eqs. (34) and (35), respectively, we have

$$(4\pi)^{10} kR' \left[\text{Diagram} \right] = -\frac{\zeta_5}{\varepsilon^2} - \frac{1}{\varepsilon} \left(\frac{5}{2} \zeta_6 + \frac{17}{5} \zeta_3^2 - 5\zeta_5 \right). \quad (43)$$

4 Calculation of massive Feynman integrals (basic formulas)

Feynman integrals with massive propagators are significantly more complicated objects compared to the massless case (see, for example, the recent review [29]). The basic rules for calculating such diagrams are discussed in Section 2, which are supplemented by new ones containing directly massive propagators.

Let us briefly consider the rules for calculating diagrams with the massive propagators. Propagator with mass M is represented as

$$\frac{1}{(q^2 + M^2)^\alpha} = \overrightarrow{q} \begin{array}{c} M \\ \alpha \end{array} \text{---}, \quad (44)$$

The following formulas hold.

A. For simple chain of two massive propagators with the same mass, we have

$$\frac{1}{(q^2 + M^2)^{\alpha_1}} \frac{1}{(q^2 + M^2)^{\alpha_2}} = \frac{1}{(q^2 + M^2)^{(\alpha_1 + \alpha_2)}},$$

or graphically

$$\overrightarrow{q} \begin{array}{c} M \\ \alpha_1 \end{array} \text{---} \begin{array}{c} M \\ \alpha_2 \end{array} \text{---} = \overrightarrow{q} \begin{array}{c} M \\ \alpha_1 + \alpha_2 \end{array} \text{---}, \quad (45)$$

i.e. the product of propagators with the same mass M is equivalent to a new propagator with the mass M and an index equal to the sum of the indices of the original propagators.

B. Massive tadpole is integrated as

$$\int \frac{Dk}{k^{2\alpha_1}(k^2 + M^2)^{\alpha_2}} = N_d \frac{R(\alpha_1, \alpha_2)}{M^{2(\alpha_1 + \alpha_2 - d/2)}}$$

where

$$R(\alpha, \beta) = \frac{\Gamma(d/2 - \alpha_1)\Gamma(\alpha_1 + \alpha_2 - d/2)}{\Gamma(d/2)\Gamma(\alpha_2)}. \quad (46)$$

C. A simple loop of two massive propagators with masses M_1 and M_2 can be represented as hypergeometric function, which can be calculated in a general form, for example, by Feynman-parameter method. With this approach, it is very convenient to represent the loop as the integral of the propagator with the “effective mass” μ [30]-[36]:

$$\begin{aligned} & (4\pi)^{d/2} \times \int \frac{Dk}{[(q-k)^2 + M_1^2]^{\alpha_1}[k^2 + M_2^2]^{\alpha_2}} \\ &= \frac{\Gamma(\alpha_1 + \alpha_2 - d/2)}{\Gamma(\alpha_1)\Gamma(\alpha_2)} \int_0^1 \frac{ds s^{\alpha_1-1} (1-s)^{\alpha_2-1}}{[s(1-s)q^2 + M_1^2 s + M_2^2(1-s)]^{\alpha_1 + \alpha_2 - d/2}} \\ &= \frac{\Gamma(\alpha_1 + \alpha_2 - d/2)}{\Gamma(\alpha_1)\Gamma(\alpha_2)} \int_0^1 \frac{ds}{s^{1-\tilde{\alpha}_2} (1-s)^{1-\tilde{\alpha}_1}} \frac{1}{[q^2 + \mu^2]^{\alpha_1 + \alpha_2 - d/2}}, \quad \left(\mu^2 = \frac{M_1^2}{1-s} + \frac{M_2^2}{s} \right). \end{aligned}$$

It is useful to rewrite the equation graphically as

$$\text{Diagram} = N_d \frac{\Gamma(\alpha_1 + \alpha_2 - d/2)}{\Gamma(\alpha_1)\Gamma(\alpha_2)} \int_0^1 \frac{ds}{s^{1-\tilde{\alpha}_2} (1-s)^{1-\tilde{\alpha}_1}} \text{Diagram} \quad (47)$$

D. For any triangle with indices α_i ($i = 1, 2, 3$) and masses M_i there is the following relation, which is based on integration by parts (IBP) procedure [18, 3, 31]

$$\begin{aligned} & (d - 2\alpha_1 - \alpha_2 - \alpha_3) \text{Diagram} \\ &= \alpha_2 \left[\text{Diagram} - \left[(q_2 - q_1)^2 + M_1^2 + M_2^2 \right] \times \text{Diagram} \right] \\ &+ \alpha_3 \left[\alpha_2 \leftrightarrow \alpha_3, M_2 \leftrightarrow M_3 \right] - 2M_1^2 \alpha_1 \times \text{Diagram} \quad (48) \end{aligned}$$

Eq. (48) can be obtained by introducing the factor $(\partial/\partial k_\mu)(k - q_1)^\mu$ to the subintegral expression of the triangle, shown below as [...], and using the integration by parts procedure as follows:

$$\begin{aligned} d \int Dk [...] &= \int Dk \left(\frac{\partial}{\partial k_\mu} (k - q_1)^\mu \right) [...] = \int Dk \frac{\partial}{\partial k_\mu} ((k - q_1)^\mu [...]) \\ &- \int Dk (k - q_1)^\mu \frac{\partial}{\partial k_\mu} ([...]) \end{aligned} \quad (49)$$

The first term in the r.h.s. becomes to be zero because it can be represented as a surface integral on the infinite surface. Evaluating the second term in the r.h.s. we reproduce Eq. (48).

As it is possible to see from Eqs. (48) and (49) the line with the index α_1 is distinguished. The contributions of the other lines are same. So, we will call below the line with the index α_1 as a “distinguished line”. It is clear that a various choices of the distinguished line produce different types of the IBP relations.

The IBP relations lead to differential equations [31, 37, 38] for the considered diagrams (see an example in Section 5) with inhomogeneous terms containing simpler diagrams, i.e. diagrams containing fewer propagators. By repeating the IBP procedure several times, in the last step we can obtain an inhomogeneous term containing only very simple diagrams, that can be calculated using the A-C rules discussed above, as well as the rules discussed in Section 2. By integrating successively inhomogeneous terms, at the last stage, one can restore the original diagrams.

E. I would also like to note the importance of the inverse-mass expansions of massive FIs depending on one mass (or on two masses in the on-shell case). The structure of the coefficients of such expansions often has some universality, preserving the complexity (or rang) of harmonic (or nested) sums [39] (a more detailed discussion can be found in a recent review [40]). This property simplifies the structure of the results (and the corresponding ansatz for it), and also makes it possible to predict the unknown terms of the expansion. This property is associated with a specific form of differential equations (see discussions in Refs. [41, 42]) and is most successfully used in the so-called canonical approach [38], which is currently the most popular.

Note also that a similar property (in reality, even more strict) takes place in the $N = 4$ Super-Yang-Mills (SYM) model not only for some master integrals, but for the kernel of the Balitsky-Fadin-Lipatov-Kuraev (BFKL) equation [43, 44], as well as for the anomalous dimensions contributed to the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) equations [45], and for Wilson coefficient functions (see, respectively, Refs. [46]-[50]). This property was called [46] the principle of maximal transcendentality and allows us to obtain anomalous dimensions of Wilson operators and Wilson coefficient functions without any calculations, directly from the corresponding QCD results (if they exist). Moreover, this property (together with the rules [51] for analytic continuation) allows predicting the ansatz [52] for finding the solution of the corresponding Bethe-ansatz [53] and obtaining results for anomalous dimensions in high orders of perturbation theory (see, respectively, Refs. [47, 48, 49, 54, 55, 56, 57]). Thus, the anomalous dimensions of the Wilson operators were found [57] in the seven-loop approximation .

5 Two-loop on-shell master integral

Consider the two-loop on-shell master integral (with $q^2 = -m^2$)

$$I(m^2, M^2) = \text{diagram} \quad (50)$$

contributing to the α_s -correction to the ratio between the pole and \overline{MS} masses of the Higgs boson in the Standard Model.

Except for special places, below we will not indicate the masses m and M , but will use rather thin and thick lines for propagators with m and M , respectively.

Applying the IBP relation for the inner loop of the integral $I(m^2, M^2)$, we have

$$(d-3) I(m^2, M^2) = \text{diagram}_1 - \text{diagram}_2 - (4M^2 - m^2) \text{diagram}_3 \quad (51)$$

It is possible to see that the last integral in the r.h.s. can be represented as

$$- \frac{1}{2} \frac{\partial}{\partial M^2} I(m^2, M^2) \quad (52)$$

and, thus, eq. (51) can be rewritten as the differential equation

$$(4M^2 - m^2) \frac{1}{2} \frac{\partial}{\partial M^2} I(m^2, M^2) = (d-3) I(m^2, M^2) + J(m^2, M^2), \quad (53)$$

where the inhomogeneous term

$$J(m^2, M^2) = \text{diagram}_4 - \text{diagram}_5 \quad (54)$$

contains only less complicated diagrams. The solution of the equation with the boundary condition $T(M^2 \rightarrow \infty, m^2) = 0$ has the following form

$$I(M^2, m^2) = N_4^2 \bar{I}(x) \frac{(\bar{\mu}^2)^{2\varepsilon}}{(m^2)^{2\varepsilon}}, \quad J(M^2, m^2) = N_4^2 \bar{J}(x) \frac{\bar{\mu}^2}{(m^2)^{2\varepsilon}}, \quad (55)$$

$$\bar{I}(x) = -(4x-1)^{1/2-\varepsilon} \int_x^\infty \frac{2\bar{I}_1(x_1) dx_1}{(4x_1-1)^{3/2-\varepsilon}} = -\frac{(4-z)^{1/2-\varepsilon}}{z^{1/2-\varepsilon}} \int_0^z \frac{2\bar{J}(z_1) dz_1}{z_1^{1/2+\varepsilon} (4-z_1)^{(3/2-\varepsilon)}}, \quad (56)$$

where

$$x = \frac{M^2}{m^2}, \quad z = \frac{M^2}{m^2} = \frac{1}{x}. \quad (57)$$

5.1 $\bar{J}(x)$

The result for the first diagram of $\bar{J}(x)$ can be written in the following form [58]:

$$\text{Diagram 1} = N_4^2 \frac{(\bar{\mu}^2)^{2\varepsilon}}{(M^2)^{2\varepsilon}} \left[\frac{1}{2\varepsilon^2} + \frac{1}{2\varepsilon} - \frac{1}{2} + \ln z + \frac{1-z}{z} \bar{\text{Li}}_2(z) \right], \quad (58)$$

where

$$\bar{\text{Li}}_2(z) = \text{Li}_2(z) + \ln z \ln(1-z) \quad (59)$$

and $\text{Li}_2(z)$ is dilogarithm [59] (more complicated functions can be found in Ref. [60]).

The result for off-shell one-loop can be presented in the form (by using, for example, the rule C)

$$\text{Diagram 2} = \frac{N_4}{(1-2\varepsilon)} \frac{(\bar{\mu}^2)^\varepsilon}{(m^2)^\varepsilon} \left[\frac{1}{\varepsilon} + \frac{1+y}{1-y} \left[\ln y + \varepsilon \left(\frac{1}{2} \ln^2 y - 2 \ln y \ln(1+y) - 2 \text{Li}_2(-y) - \zeta_2 \right) \right] \right], \quad (60)$$

where y is so-called conformal variable (see Appendix A with the replacement $m^2 \rightarrow -q^2$), which is very convenient in the case of massive FIs (see, for example, [30, 35, 61])

Taking on-shell limit (see also Appendix A), i.e.

$$z = 1, \quad y = \frac{\sqrt{3}+i}{\sqrt{3}+i}, \quad \frac{1+y}{1-y} = \frac{\sqrt{3}}{i}, \quad \ln y = -\frac{\pi i}{3}, \quad \text{Li}_2(-y) = -\frac{1}{3}\zeta_2 + \frac{2i}{3} \text{Cl}_2\left(\frac{\pi}{3}\right) \quad i^2 = -1, \quad (61)$$

where $\text{Cl}_2(\pi/3)$ is the Clausen function, we have

$$\text{Diagram 3} = \frac{N_4}{(1-2\varepsilon)} \frac{(\bar{\mu}^2)^\varepsilon}{(m^2)^\varepsilon} \left[\frac{1}{\varepsilon} - a_1 - a_2 \varepsilon \right], \quad (62)$$

with

$$a_1 = -\frac{\pi}{\sqrt{3}}, \quad a_2 = \frac{4}{\sqrt{3}} \text{Cl}_2\left(\frac{\pi}{3}\right) - \frac{\pi}{\sqrt{3}} \ln 3. \quad (63)$$

Then, the result for the second diagram of $\bar{J}(x)$ can be written in the following form

$$\text{Diagram 4} = \frac{N_4^2}{(1-2\varepsilon)} \frac{(\bar{\mu}^2)^{2\varepsilon}}{(M^2)^\varepsilon (m^2)^\varepsilon} \left[\frac{1}{\varepsilon^2} - \frac{a_1}{\varepsilon} - a_2 \right]. \quad (64)$$

Thus, for $\bar{J}(x)$ we have the following result

$$\bar{J}(z) = \left[-\frac{1}{2\varepsilon^2} + \left(a_1 - \frac{3}{2} \right) \frac{1}{\varepsilon} + a_2 + 2a_1 - \frac{9}{2} + a_1 \ln z + \frac{1-z}{z} \bar{\text{Li}}_2(z) + \frac{1}{2} \ln^2 z \right]. \quad (65)$$

5.2 $\bar{I}(x)$

To find the result for the initial diagram $\bar{I}(x)$, see Eq. (56), we have to calculate several integrals.

The first integrals, which corresponds to z -independent part of $\bar{J}(x)$, is very simple:

$$\bar{I}_1(x) = (4x - 1)^{1/2-\varepsilon} \int_x^\infty \frac{dx_1}{(4x_1 - 1)^{3/2-\varepsilon}} = \frac{1}{2(1-2\varepsilon)}. \quad (66)$$

Other integrals can be calculate at the accuracy $\varepsilon = 0$. The integral $\sim \ln z$ in $\bar{J}(x)$ can be evaluated using integration by parts² as

$$\bar{I}_2(x) = (4x - 1)^{1/2} \int_x^\infty \frac{dx_1}{(4x_1 - 1)^{3/2}} \ln\left(\frac{1}{x_1}\right) = \frac{1}{2} \left[\ln\left(\frac{1}{x}\right) - \tilde{I}(x) \right], \quad (67)$$

where (see Appendix A)

$$\begin{aligned} \tilde{I}(x) &= (4x - 1)^{1/2} \int_x^\infty \frac{dx_1}{x_1(4x_1 - 1)^{1/2}} = \frac{(4 - z)^{1/2}}{z^{1/2}} \int_0^z \frac{dz_1}{z_1^{1/2}(4 - x_1)^{1/2}} \\ &= \frac{2}{t} \int_0^t \frac{dt_1}{1 + t_1^2} = -\frac{1 + y}{1 - y} \ln y \end{aligned} \quad (68)$$

and, thus,

$$\bar{I}_2(x) = \frac{1}{2} \left[\ln z + \frac{1 + y}{1 - y} \ln y \right]. \quad (69)$$

The integral $\sim \ln^2 z$ in $\bar{J}(x)$ can be evaluated using integration by parts similarly to the previous one. We have

$$\bar{I}_3(x) = (4x - 1)^{1/2} \int_x^\infty \frac{dx_1}{(4x_1 - 1)^{3/2}} \ln^2\left(\frac{1}{x_1}\right) = \frac{1}{2} \left[\ln^2\left(\frac{1}{x}\right) + 2\tilde{I}_1(x) \right], \quad (70)$$

where (see Appendix A)

$$\begin{aligned} \tilde{I}_1(x) &= (4x - 1)^{1/2} \int_x^\infty \frac{dx_1}{x_1(4x_1 - 1)^{1/2}} \ln x_1 = -\frac{(4 - z)^{1/2}}{z^{1/2}} \int_0^z \frac{dz_1}{z_1^{1/2}(4 - x_1)^{1/2}} \ln z_1 \\ &= -\frac{2}{t} \int_0^t \frac{dt_1}{1 + t_1^2} \ln[z_1(t_1)] = -\frac{1 + y}{1 - y} \int_y^1 \frac{dy_1}{y_1} \ln[z_1(y_1)]. \end{aligned} \quad (71)$$

The last integral can be calculated using integration by parts as

$$-\int_y^1 \frac{dy_1}{y_1} \ln[z_1(y_1)] = \ln y \ln z - \int_y^1 \frac{dy_1(1 + y_1)}{y_1(1 - y_1)} \ln y_1 = \ln y \ln z + \frac{1}{2} \ln^2 y + 2\text{Li}_2(1 - y) \equiv T_1(y), \quad (72)$$

²A similar application of the integration by parts procedure for integral representations can be found in the recent article [62], where FIs containing elliptic structures were considered.

and, thus,

$$\tilde{I}_1(x) = \frac{1+y}{1-y} T_1(y) \quad \text{and} \quad \bar{I}_3(x) = \frac{1}{2} \ln^2 z + \frac{1+y}{1-y} T_1(y). \quad (73)$$

The last term $\sim \bar{\text{Li}}_2(z)$ in $\bar{J}(x)$ can be evaluated using integration by parts similarly to the previous ones. It can be represented in the form

$$\bar{I}_4(x) = (4x-1)^{1/2} \int_x^\infty \frac{dx_1 (x_1-1)}{(4x_1-1)^{3/2}} \bar{\text{Li}}_2(1/x_1) = \frac{1}{2} \left[-\frac{2+z}{2z} \bar{\text{Li}}_2(z) + \tilde{I}_2(x) \right], \quad (74)$$

where

$$\begin{aligned} \tilde{I}_2(x) &= -(4x-1)^{1/2} \int_x^\infty \frac{dx_1 (x_1+1/2)}{x_1 (4x_1-1)^{1/2}} \frac{\partial}{\partial x_1} \bar{\text{Li}}_2(1/x_1) \\ &= \frac{(4-z)^{1/2}}{z^{1/2}} \int_0^z \frac{dz_1 (2+z_1)}{2z_1^{1/2} (4-z_1)^{1/2}} \frac{\partial}{\partial z_1} \bar{\text{Li}}_2(z_1) \end{aligned} \quad (75)$$

Since

$$\frac{\partial}{\partial z} \bar{\text{Li}}_2(z) = -\frac{\ln z}{1-z} \quad (76)$$

we have

$$\begin{aligned} \tilde{I}_2(x) &= -\frac{(4-z)^{1/2}}{z^{1/2}} \int_0^z \frac{dz_1 (2+z_1)}{2z_1^{1/2} (4-z_1)^{1/2}} \frac{\ln z_1}{1-z_1} = -\frac{2}{t} \int_0^t \frac{dt_1 (1+3t_1^2)}{(1+t_1^2)(1-3t_1^2)} \ln[z_1(t_1)] \\ &= \frac{1}{t} \int_0^t dt_1 \left[\frac{1}{1+t_1^2} - \frac{3}{1-3t_1^2} \right] \ln[z_1(t_1)] = -\frac{1}{2} \frac{1+y}{1-y} T_1(y) - 3\tilde{I}_{21}(x). \end{aligned} \quad (77)$$

Now we study the term $\tilde{I}_{21}(x)$. Considering the integral

$$\int_0^t dt_1 \frac{1}{1-3t_1^2} = -\frac{1}{2\sqrt{3}} \ln \left(\frac{1-\sqrt{3}t}{1+\sqrt{3}t} \right), \quad (78)$$

we see an appearance of the new variable

$$\xi = \frac{1-\sqrt{3}t}{1+\sqrt{3}t} \quad (79)$$

Using the new variable ξ (see Appendix A), we have for $\tilde{I}_{21}(x)$:

$$\tilde{I}_{21}(x) = \frac{1}{2\sqrt{3}t} \int_\xi^1 \frac{d\xi_1}{\xi_1} \ln \left(\frac{(1-\xi_1)^2}{(1+\xi_1+\xi_1^2)} \right) \quad (80)$$

Since

$$\frac{(1-\xi_1)^2}{(1+\xi_1+\xi_1^2)} = \frac{(1-\xi_1)^3}{(1-\xi_1^3)} \quad \text{and} \quad \frac{1}{\sqrt{3}t} = \frac{1+\xi}{1-\xi}, \quad (81)$$

we can evaluate the integral $\tilde{I}_{21}(x)$ in the following form ³

$$\tilde{I}_{21}(x) = \frac{1+\xi}{2(1-\xi)} \left[3\text{Li}_2(\xi) - \frac{1}{3} \text{Li}_2(\xi^3) - \frac{8}{3} \zeta_2 \right] \equiv \frac{1+\xi}{2(1-\xi)} T_2(\xi) \quad (82)$$

³We see the appearance of a polynomial structure $(1+\xi_1+\xi_1^2)$ in the integrand (80), which leads to the appearance of the polylogarithms with the argument ξ^3 below in (82). A similar polynomial structure has already been developed, for example, in Refs. [30, 36, 63, 64] and in the more complicated cases the structure leads to the appearance of the cyclotronic polylogarithms [65, 66].

and, thus,

$$\begin{aligned}\tilde{I}_2(x) &= -\frac{1+y}{2(1-y)} T_1(y) - \frac{3(1+\xi)}{2(1-\xi)} T_2(\xi), \\ \bar{I}_4(x) &= -\frac{2+z}{4z} \bar{\text{Li}}_2(z) - \frac{1+y}{4(1-y)} T_1(y) - \frac{3(1+\xi)}{4(1-\xi)} T_2(\xi)\end{aligned}\quad (83)$$

Thus, the initial master integral $\bar{I}(x)$ can be expressed as

$$\begin{aligned}\bar{I}(x) &= \frac{1}{2} \left(\frac{1}{\varepsilon^2} + \frac{5-2a_1}{\varepsilon} + 19 - 8a_1 - 2a_2 \right) - a_1 \left[\ln z + \frac{1+y}{1-y} \ln y \right] - \frac{1}{2} \ln^2 z \\ &+ \frac{2+z}{2z} \bar{\text{Li}}_2(z) - \frac{1+y}{2(1-y)} T_1(y) + \frac{3(1+\xi)}{2(1-\xi)} T_2(\xi)\end{aligned}\quad (84)$$

6 Conclusion

In this short review, we have presented the results of calculating some massless and massive Feynman integrals.

In the massless case, we considered a 5-loop master diagram that contributes to the β -function of the φ^4 -model. The results for this diagram were obtained [4, 5] by Dmitry Kazakov, but it published without any intermediate calculations. Our calculations are performed in detail (the other two diagrams were discussed in [8]) and the final result coincides with that obtained by Kazakov.

In the massive case, we considered the computation of one of the master integrals contributing to the relationship between the \overline{MS} -mass and the pole-mass of the Higgs boson in the Standard Model in the limit of heavy Higgs. The results for this master integral contain dilogarithms with unusual arguments.

The author is grateful to Mikhail Kalmykov for collaboration in the calculation of on-shell diagrams, as well as for the correspondence. The author is grateful also to Andrei Pikelner for him help with Axodraw2.

7 Appendix A

Here we present the sets of the new variables that are useful for integrations in the case of massive diagrams:

$$\begin{aligned}t^2 &= \frac{z}{4-z}, \quad z = \frac{4t^2}{1+t^2}, \quad 4-z = \frac{4}{1+t^2}, \quad (dz) = \frac{8t(dt)}{(1+t^2)^2}; \\ y &= \frac{1-it}{1+it}, \quad t = \frac{1-y}{i(1+y)}, \quad 1+t^2 = \frac{4y}{(1+y)^2}, \quad (dt) = -\frac{2}{i} \frac{(dy)}{(1+y)^2}, \quad \frac{(dt)}{1+t^2} = -\frac{1}{2i} \frac{(dy)}{y}; \\ \xi &= \frac{1-\sqrt{3}t}{1+\sqrt{3}t}, \quad t = \frac{1}{\sqrt{3}} \frac{1-\xi}{1+\xi}, \quad z = \frac{4t^2}{1+t^2} = \frac{(1-\xi)^2}{1+\xi+\xi^2} = \frac{(1-\xi)^3}{1-\xi^3}, \\ (dt) &= -\frac{2(dy)}{\sqrt{3}(1+y)^2}, \quad \frac{(dt)}{1-3t^2} = -\frac{1}{2\sqrt{3}} \frac{(d\xi)}{\xi}.\end{aligned}\quad (A1)$$
